Subject:

Summary of Groundwater Monitoring Activities; Earl Manufacturing, 11862

Burke Street, Santa Fe Springs

Dear Ms. Earl:

This letter constitutes SCS Engineers' (SCS) report of groundwater monitoring well installation, development, and sampling in the immediate vicinity of the former underground storage tank (UST). The purpose of the single monitoring well was to assess potential impacts to groundwater in a "worst case" location.

Groundwater Monitoring Well Installation and Development

A hollow-stem auger drill rig, operated by Layne Christensen Company, was mobilized to the site under SCS oversight to install one well to a depth of 42 feet below ground surface (bgs) in an area immediately south of the main building (Figures 1, Appendix A). Soil samples were collected at 5-foot intervals for visual examination using a Modified California Sampler (split spoon). A copy of the boring log is included in Appendix B. The well was constructed of 2-inch diameter Schedule 40 PVC, screened with 0.010-inch wide factory slotted Schedule 40 PVC from approximately 22 to 42 feer bgs. A filter pack of No. 2/16 sand was placed in the annular space surrounding the screen. The sand was filled to 3-feet above the top of the screen. A 3-foot thick bentonite seal was placed above the filter pack, followed by bentonite cement grout to the surface. A flush-mounted traffic-rated locking well box was cemented in place above the casing. Figure 3 (Appendix A) provides an example of typical well construction details.

Following well construction, the bentonite-cement grout was allowed to cure for 8 days. After this time period, the well was developed to remove the finer material from the formation and filter pack surrounding the well. Development consisted of a combination of surging and bailing which continued until relatively clear water (i.e. few observable fine materials) was obtained. First, the well was bailed to remove standing water and any sediment within the casing. A surge block was used to home water into and out of the well screen. This removed fine sediment surrounding the well screen and improved the flow characteristics of the well. The surge block and bailer was steam cleaned prior to being introduced to the well.

Ms. Claudette Earl December 13, 1999 Page 2

After surging, the well was bailed again until the water removed was relatively free of sediment. Soil cuttings and development water were drummed and left on site.

Groundwater Sampling and Analysis

Prior to initiating sampling activities, SCS measured the static water level using a water level indicator. The water level indicator was cleaned prior to measuring the water level in the well using a non-phosphate biodegradable detergent and fresh tap water, followed by a distilled or deionized water rinse. Depth to water, water surface elevation, and purging information was recorded on a field data sheet which is included in Appendix C of this document.

The well to be sampled, MW-1, was purged of a minimum of 3 casing volumes using a dedicated polyethylene disposable bailer, prior to sample collection. During purging, measurements of temperature, specific conductivity, turbidity, and pH were recorded in well sampling logs to ensure stabilization of groundwater conditions before sampling.

After purging, groundwater samples were collected by using a dedicated polyethylene disposable bailer attached to a nylon cord. Groundwater samples were placed in appropriate pre-cleaned containers obtained from the analytical laboratory. For this investigation groundwater samples were collected in 40 ml glass VOA bottles. New disposable latex sample gloves were used during sample collection. Samples were labeled and immediately placed in a refrigerated cooler for transport to Advanced Technology Laboratory, a state-certified analytical laboratory, where one sample was analyzed for volatile organic compounds by EPA Method 8260 within the appropriate holding time. Laboratory results and a copy of the chain-of-custody form are included in Appendix D.

Laboratory Results

Analysis indicates a concentration of tetrachloroethene (PCE) of 13,700 ug/l (micrograms per liter; equivalent to parts per billion) and of trichloroethene (TCE) of 1,730 ug/l. In addition, trace concentrations of 1,1,1-trichloroethane and 1,1-dichloroethene were detected. Maximum contaminant levels specified by State regulations for drinking water are 5 ug/l for either PCE or TCE.

Interpretation of Results

Both PCE and TCE were detected in groundwater in concentrations that would be considered significantly elevated by the Regional Water Quality Control Board (RWQCB).

Ms. Claudette Earl December 13, 1999 Page 3

Although detectable concentrations of PCE and TCE might be expected in groundwater in many areas of Santa Fe Springs, and although low concentrations (up to several tens of parts per billion) might be considered "background" in shallow groundwater in some areas of the city, the concentrations detected in the sample collected are significantly higher than what might be expected as a background level. In addition, the fact that PCE was detected previously in soil samples from the UST area is likely to be interpreted by RWQCB staff as indicating the UST was the source of the PCE in groundwater.

Conclusions

Based on the detected PCE and TCE in groundwater, it appears unlikely that closure will be granted by the RWQCB in the near future. Prior to considering closure, it seems likely that RWQCB would request installation of additional wells (perhaps one upgradient and one further downgradient or to the west) and sampling of all wells once per calendar quarter for a minimum of one year. Additional investigative activities might also be requested.

If you have any questions, please feel free to call.

Very truly yours.
